Abstract

Natural gas (NG) is the cleanest burning fossil fuel and its usage can significantly reduce CO2 emissions from power plants. With its widespread use, there is an ever increasing need to develop technologies to store NG on a large scale. NG storage via clathrate hydrates is the best option for a large scale storage system because of its non-explosive nature, mild storage conditions, high volumetric capacity and being an environmentally benign process. In this work, we demonstrate a new method to achieve rapid methane hydrate formation in an unstirred tank reactor configuration (UTR) at moderate temperature and pressure conditions employing tetrahydrofuran (THF) as a promoter. For the first time, THF is reported to act both as a thermodynamic and an excellent kinetic promoter for methane hydrate formation. We demonstrate a multi-scale experimental validation of our method to a volumetric sample scale-up factor of 120 and internal reactor diameter scale-up factor of 10. Further, new insights on the dissociation behavior of the hydrates are reported. There is a competitive edge for storing NG via clathrate hydrates compared to compressed natural gas storage both in terms of cost and safety. (C) 2016 Elsevier B.V. All rights reserved.

Highly Cited Thresholds

The highly cited threshold is the minimum number of citations received by the top 1% of papers in the research field published in the specified year.

Sample Report

In the following report, the top 1% of papers in Physics added to Web of Science in 2010 received at least 44 citations. The top 1% of papers in Plant & Animal Science added to Web of Science in 2011 received at least 16 citations. Articles citing the 2010 papers may have been published between 2010 and 2013. Articles citing the 2011 papers may have been published between 2011 and 2013.
